Forward-looking Statements

Any statements in this presentation about the Company's future expectations, plans and prospects constitute forward-looking statements for purposes of the safe harbor provisions under the Private Securities Litigation Reform Act of 1995. Forward-looking statements include any statements about the Company's strategy, future operations and future expectations and plans and prospects for the Company, and any other statements containing the words "anticipate," "believe," "estimate," "expect," "intend", "goal," "may", "might," "plan," "predict," "project," "seek," "target," "potential," "will," "would," "could," "should," "continue," and similar expressions. In this presentation, the Company's forward looking statements include statements about its expectations to use its previously announced clinical trial of Zimura for the treatment of geographic atrophy as a pivotal trial, its development strategy for Zimura, the Company's hypotheses regarding complement inhibition as a mechanism of action for the treatment of geographic atrophy, the projected use of cash and cash balances, the timing, progress and results of clinical trials and other research and development activities, the potential utility of its product candidates, estimates regarding the number of patients affected by the diseases and indications the Company's product candidates are intended to treat, and statements regarding the potential for the Company's business development strategy. Such forward-looking statements involve substantial risks and uncertainties that could cause the Company's development programs, future results, performance or achievements to differ significantly from those expressed or implied by the forward-looking statements. Such risks and uncertainties include, among others, those related to the initiation and the progress of research and development programs and clinical trials, availability of data from these programs, reliance on university collaborators and other third parties, establishment of manufacturing capabilities, expectations for regulatory matters, need for additional financing and negotiation and consummation of business development transactions and other factors discussed in the "Risk Factors" section contained in the quarterly and annual reports that the Company files with the Securities and Exchange Commission. Any forward-looking statements represent the Company's views only as of the date of this presentation. The Company anticipates that subsequent events and developments will cause its views to change. While the Company may elect to update these forward-looking statements at some point in the future, the Company specifically disclaims any obligation to do so except as required by law.

Geographic Atrophy Secondary to Dry AMD: A True Epidemic

Jordi Monés MD, PhD

Institut de la Macula I de la Retina
Barcelona Macula Foundation

Retinal anatomy

Retinal anatomy

Normal fundus

Age-related macular
degeneration

Age-related macular degeneration (AMD)

Classically advanced AMD is classified into two general subgroups: the non-neovascular (atrophic or dry) type and the neovascular (exudative or wet).

Exudative or wet

Normal

Atrophic or dry

BECKMAN CLASSIFICATION AMD

Table 2. Proposed AMD Clinical Classification

Classification of AMD	Definition (lesions assessed within 2 disc diameters of fovea in either eye)
No apparent aging changes	No drusen and No AMD pigmentary abnormalities*
Normal aging changes	Only drupelets (small drusen ≤ 63 μm) and No AMD pigmentary abnormalities*
Early AMD	Medium drusen $> 63 \mu\text{m}$ and ≤ 125 μm and No AMD pigmentary abnormalities*
Intermediate AMD	Large drusen $> 125 \mu\text{m}$ and/or Any AMD pigmentary abnormalities*
Late AMD	Neovascular AMD and/or Any geographic atrophy

AMD = age-related macular degeneration.
*AMD pigmentary abnormalities = any definite hyper- or hypopigmen-
tary abnormalities associated with medium or large drusen but not asso-
ciated with known disease entities.

AGING CHANGES

EARLY AMD

INTERMEDIATE AMD

LATE AMD

Atrophic AMD

**...geographic atrophy progresses with a mean of 1.5 to 2.8
mm²/year...**

Atrophic AMD

...and there is NO treatment available...

Visual function in atrophic AMD

Visual function disability underestimated...

...visual acuity a poor endpoint...

Visual function in atrophic AMD

Although VA under estimated short-term decline in visual function:

- **30% 3 lines VA loss by 2 years**
- **55% 3 lines VA loss by 4 years**
- **25% of eyes with 20/50 or better decline to 20/200 or worse by 4 years**

Enlargement of atrophy and visual acuity loss in the geographic atrophy form of age-related macular degeneration Sunness, Janet S. et al. Ophthalmology, Volume 106, Issue 9, 1768 - 1779

Natural history progression

Impact in quality of life

Patients with 20/200 or worse vision in one eye would trade 1 of 3 remaining years to avoid the same scenario in the fellow eye

Zimura Pivotal Trial: Design and Outcome

Kourous A. Rezaei, MD
Chief Medical Officer

Pivotal Trial Highlights

Zimura Pivotal Trial in geographic Atrophy Secondary to AMD

- Both Zimura 2mg and 4mg were well tolerated over 12 months
- Primary efficacy endpoint was achieved for both Zimura 2mg and Zimura 4mg dose, leading to a ~27% reduction in GA growth over 12 months
- The overall data suggested a dose response relationship
- Initiating the second pivotal clinical trial with the goal of enrolling the first patient in the first quarter of 2020

Zimura Pivotal Clinical Trial for GA Secondary to Dry AMD

A Randomized, Double-Masked, Sham Controlled Trial to Assess the Safety and Efficacy of Intravitreal Administration of Zimura (Complement C5 Inhibitor) in Subjects with Geographic Atrophy Secondary to Dry Age-Related Macular Degeneration (AMD)

Screening Clinical Trial Design

- If the estimated effect size indicates low levels of benefit: would not move forward with a subsequent trial
- If the estimated effect size is moderate, but clinically relevant: move forward with subsequent Phase 3 clinical trials
- If the estimated effect size is more efficacious than the sham control with the strength of evidence meeting the level of statistical significance, as was the case in the Zimura trial for both the 2 mg and 4 mg dose groups, then the trial could potentially serve as a registration trial and only one more pivotal trial would be required for regulatory approval

Zimura in GA Secondary to Dry AMD Pivotal Clinical Trial

- Randomized, double masked, sham controlled clinical trial
- Cohorts included in the pre-specified statistical analysis of the primary endpoint at Month 12*:
 - Zimura 4 mg dose
 - Zimura 2 mg dose
 - Sham
- 286 subjects were enrolled for monthly treatment with Zimura or Sham for 18 months
 - ~75% of the patients were enrolled in the US

*Descriptive analysis was performed for the Zimura 1mg cohort

Primary Efficacy Endpoint

Mean rate of change in GA over 12 months measured by fundus autofluorescence (FAF) at three time points: Baseline, Month 6, and Month 12 (square root transformation of GA lesion)

Primary Efficacy Endpoint

- GA: Visual function can be a poor indicator of functional vision
- Patients' visual disabilities are usually underestimated

Primary Efficacy Endpoint

- GA: Visual function can be a poor indicator of functional vision
- Patients' visual disabilities are usually underestimated

Duke Reading Center: Imaging Analysis Overview

- Completely masked assessment
- Each visit was evaluated independently
- Two experienced primary readers analyze the GA lesion size on FAF with RegionFinder
- > 10% discrepancy will be arbitrated by Reading Center Director: Glenn Jaffe, MD
- Supportive modalities: OCT and NIR imaging

- Zimura 4 mg vs. Sham: based only on subjects randomized in Part 2

Zimura in GA Secondary to Dry AMD Clinical Trial

Part 1:

Part 2:

Key Ophthalmic Inclusion Criteria (Study Eye)

- Non-foveal GA secondary to dry AMD
- Total GA area ≥ 2.5 and ≤ 17.5 mm² (1 and 7 disk areas [DA] respectively), determined by screening images of FAF
- If GA is multifocal, at least one focal lesion should measure ≥ 1.25 mm² (0.5 DA)
- GA in part within 1500 microns from the foveal center
- The atrophic lesion must be able to be photographed in its entirety
- Best corrected visual acuity in the SE between 20/25 – 20/320, inclusive

Key Ophthalmic Exclusion Criteria

- GA secondary to any condition other than AMD in either eye (e.g., drug-induced)
- Any prior treatment for AMD or any prior intravitreal treatment for any indication in either eye, except oral supplements of vitamins and minerals
- Evidence of CNV in either eye. If CNV develops in the SE during the course of the study, the subject will be withdrawn from the study
- Any ocular condition in the SE that would progress during the course of the study that could affect central vision or otherwise be a confounding factor

Statistical Analysis

- A Mixed -Effects Repeated Measures (MRM) model was used to assess the differences between Zimura 2mg or 4mg dose and their corresponding sham in rate of change of GA area (square root transformation) over 12 months
- The model included the following fixed and *random effects*:
 - Treatment: Sham vs dose
 - Study part (1 vs 2): only for 2 mg
 - Baseline VA: < 50 letters vs ≥ 50 letters
 - Size of baseline GA: < 4 disc area vs ≥ 4 disc area
 - Pattern of FAF at the junctional zone of GA: none/focal vs banded/diffuse
 - *Visit (0, 6 mos or 12 mos) with unstructured correlation*
 - *Interaction terms between visit and all other factors*

Baseline Characteristics: Generally Balanced Across Cohorts*

	Zimura 2mg N = 67	Sham for 2mg arm N = 110	Zimura 4mg N = 83	Sham for 4mg arm N = 84
Mean Age, Years	78.8	78.2	79.2	78.2
Female Gender, Number (%)	45 (67.2%)	79 (71.8%)	58 (69.9%)	61 (72.6%)
Active smoker, Number (%)	25 (37.3%)	36 (32.7%)	26 (31.3%)	29 (34.5%)
Non-Subfoveal GA, Number (%)	62 (92.5%)	104 (94.5%)	81 (97.6%)	82 (97.6%)
Mean GA Area, mm ²	7.33	7.42	7.90	7.45

*Detailed baseline characteristics based on part 1 and part 2 are available online

Preliminary Safety Analysis Through Month 12

- Zimura was generally well tolerated after 12 months of administration
- No Zimura related adverse events
- No Zimura related inflammation
- No drug related discontinuations from the trial attributed to Zimura
- No serious ocular adverse events in the study eye
- No cases of endophthalmitis reported in the clinical trial
- The most frequently reported ocular adverse events were related to the injection procedure
- Incidence of CNV in the untreated fellow eyes was 10 patients (3.5%) and in the study eyes was 3 patients (2.7%) in the sham group, 1 patient (4.0%) in the Zimura 1mg group, 6 patients (9.0%) in the Zimura 2mg group, and 8 patients (9.6%) in the Zimura 4mg group

Primary Efficacy Endpoint Achieved for Both Zimura 2mg and 4mg

Mean Rate of Change in Geographic Atrophy Area from Baseline to Month 12 (MRM Analysis) (Square Root Transformation, ITT Population)

Cohort	Zimura 2 mg (N = 67 ^(c))	Sham 2 mg (N = 110 ^(c))	Difference	P-value	% Difference
Mean Change in GA ^(a) (mm)	0.292	0.402	0.110	0.0072 ^(b)	27.38%

Cohort	Zimura 4 mg (N = 83)	Sham 4 mg (N = 84)	Difference	P-value	% Difference
Mean Change in GA ^(a) (mm)	0.321	0.444	0.124	0.0051 ^(b)	27.81%

(a) = based on the least squared means from the MRM model

(b) = reflects statistically significant p-value; Hochberg procedure was used for significance testing

(c) = these least square means are estimates of the MRM model, drawing on all available data, including data from groups with different randomization ratios in Part 1 and Part 2, and should not be interpreted as directly observed data

Primary Endpoint Achieved: Zimura 2 mg vs. Sham

Mean Rate of Change in GA for Zimura 2 mg by Part

Mean Rate of Change in Geographic Atrophy (GA) Area from Baseline to Month 12 (MRM Analysis) (Square Root Transformation)

Cohort		Zimura 2mg (N = 25)	Sham 2mg (N = 26)	Difference

Part 2	Mean Change in GA ^(a) (mm)	0.308	0.422	0.114
(a) = based on the least squared means from the MRM model				

Primary Endpoint Achieved: Zimura 4 mg vs. Sham

Supportive Efficacy Endpoint: Zimura 2 mg vs. Sham (Non-Square Root)

Supportive Efficacy Endpoint: Zimura 4 mg vs. Sham (Non-Square Root)

Secondary Endpoints

- Mean change in best corrected visual acuity (ETDRS letters) from Baseline to Month 12

Cohort	Zimura 2mg (N = 67)	Sham 2mg (N = 110)	Difference
Mean Change in BCVA ^(a)	-7.90 ^(b)	-9.29 ^(b)	1.39

Cohort	Zimura 4mg (N = 83)	Sham 4mg (N = 84)	Difference
Mean Change in BCVA ^(a)	-3.79	-3.51	-0.28

- Mean change in low luminance best corrected visual acuity (ETDRS letters) from Baseline to Month 12

Cohort	Zimura 2mg (N = 67)	Sham 2mg (N = 110)	Difference
Mean Change in LL BCVA ^(a)	-1.03 ^(b)	-1.41 ^(b)	0.38

Cohort	Zimura 4mg (N = 83)	Sham 4mg (N = 84)	Difference
Mean Change in LL BCVA ^(a)	1.53	2.97	-1.44

(a) = based on the least squared means from the MRM model; ITT population

(b) = these least square means are estimates of the MRM model, drawing on all available data, including data from groups with different randomization ratios in Part 1 and Part 2, and should not be interpreted as directly observed data

Trial not designed to demonstrate differences in mean changes in BCVA or LL BCVA with statistical significance

Analyzed Geographic Atrophy Data

	N (%) ¹
Missing at baseline ²	1 (<1%)
Missing at 6 months and at 12 months ²	36 (14%)
Missing at 6 months only	11 (4%)
Missing at 12 months only	30 (12%)
No missing	182 (70%)
	260 (100%)

¹Sham, 2mg and 4mg groups

²Excluded from model for 2mg and 4mg

Sensitivity Analyses

Several pre-specified analyses conducted for primary endpoint:

- Replaced missing data using multiple imputations, with an added “shift” increased until significance is lost
- Replaced missing data by
 - mean value of same treatment arm
 - mean value of opposite treatment arm
 - mean value of both treatment arms
 - mean value of sham arm
- Replaced missing data using “pattern mixture model”
(useful to investigate “missing not at random” assumptions)

Sensitivity Analyses

Replace missing data using multiple imputations, with an added “shift” increase until significance is lost

Data Imputation Method	Zimura 2mg vs. Sham		Zimura 4mg vs. Sham	
	Difference**	<i>P</i>	Difference**	<i>P</i>
No imputation (primary analysis)	0.110	0.0072*	0.124	0.0051*
Impute mean value of same arm	0.119	0.0005*	0.152	<0.0001*
Impute mean value of opposite arm	0.075	0.031*	0.107	0.0033*
Impute mean value of both arms	0.097	0.0047*	0.129	0.0003*
Impute mean value of sham arm	0.093	0.0056*	0.120	0.0008*

* Statistically significant (without adjustment for multiplicity)

** Difference in means of GA area (square root transformation)

Sensitivity Analyses

Statistical interpretation:

- All analyses showed small impact of missing data on our overall conclusion on the primary endpoint
- The shift imputation analyses showed that statistical significance would only be lost for large shifts (~40% of observed treatment effect)
- Analysis results were robust to missing data

Conclusions

Zimura Pivotal Trial in geographic Atrophy Secondary to AMD

- Both Zimura 2mg and 4mg were well tolerated over 12 months
- Primary efficacy endpoint was achieved for both Zimura 2mg and Zimura 4mg dose, leading to a ~27% reduction in GA growth over 12 months
- The overall data suggested a dose response relationship
- Initiating the second pivotal clinical trial with the goal of enrolling the first patient in the first quarter of 2020

Initiating Second Pivotal Trial: Planning to Begin Enrolling 1Q 2020

- Our understanding of the regulatory requirements for registration*:
 - **Safety**
 - Rule of 3: To identify adverse events occurring at a rate of 1% or greater:
 - 300 patients exposed to the dose seeking approval (or a higher dose) for a duration of at least 1 year
 - These patients do not need to be only treated for the indication seeking approval
 - A portion of these patients need to be followed for 2 years
 - **Efficacy:** Adequate and well controlled trials
 - Clear statement of the objectives: Slowing down the progression of GA growth
 - Valid Comparison and minimize bias:
 - Two independent randomized, double masked, sham controlled clinical trials
 - Well defined and reliable method of assessment for primary endpoint:
 - Objective endpoint
 - Progression of geographic atrophy over 12 months, measured at 3 timepoints
 - Assessed by an independent and masked reading center
 - Robust statistical analysis to show effect (statistical significance)

Thank You!

Zimura Pivotal Trial in Geographic Atrophy Statistical Analysis

Marc Buyse, ScD

Chief Scientific Officer, International Drug Development Institute (IDDI)

Chief Scientific Officer, Clue Points

Associate Professor of Biostatistics

Hasselt University, Belgium

Statistical Take Home Messages

- Statistically significant reductions in GA growth for both 2 mg and 4 mg doses, using mixed effects model
- Little difference in efficacy between 2 mg and 4 mg doses
- Analysis results robust to missing data
- Magnitude of effect may justify independent confirmation in a single additional pivotal trial

Study Design

Part 1: subjects were randomized in a 1:1:1 ratio to

- Zimura 1 mg/eye (N=26)
- Zimura 2 mg/eye (N=25)
- Sham (N=26)

Part 2: subjects were randomized in a 1:2:2 ratio to

- Zimura 2 mg/eye + Sham (N=42)
- Zimura 4 mg/eye (two injections of Zimura 2 mg/eye) (N=83)
- Sham + Sham (N=84)

Analysis by “Intention To Treat”: all randomized patients included

Sample Size

Sample size was calculated so that if the estimated rate of GA growth over 12 months for either 2 mg or 4 mg dose of Zimura vs. Sham were

- $< 14\%$, then this dose of Zimura would not be considered to have sufficient efficacy
- $\geq 14\%$ and $< 24.5\%$, then this dose of Zimura would be considered promising enough to be evaluated in a subsequent phase 3 clinical trial
- **$\geq 24.5\%$, then this dose of Zimura would be statistically significantly more effective than Sham**

Primary Analysis – 4 mg

A Mixed-Effects Repeated Measures (MRM) model was used to assess the differences between Zimura 4 mg and Sham in rate of change of GA area (square root transformation) over 12 months

The model included the following fixed and *random effects*:

- Treatment: Zimura 4 mg vs Sham
- Baseline VA: < 50 letters vs ≥ 50 letters
- Size of baseline GA: < 4 disc area vs ≥ 4 disc area
- Pattern of FAF at the junctional zone of GA: none/focal vs banded/diffuse
- *Visit (0, 6 mos or 12 mos) with unstructured correlation*
- *Interaction terms between visit and all other factors*

Primary Analysis – 2 mg

Because 2 mg was compared with Sham in both Part 1 and Part 2, a factor was added to the model to adjust for differences between Part 1 and Part 2 (randomization ratios 1:1 and 1:2)

The model included the following fixed and *random effects*:

- Treatment: Zimura 2 mg vs Sham
- **Study part: Part 1 vs Part 2**
- Baseline VA: < 50 letters vs ≥ 50 letters
- Size of baseline GA: < 4 disc area vs ≥ 4 disc area
- Pattern of FAF at the junctional zone of GA: none/focal vs banded/diffuse
- *Visit (0, 6 mos or 12 mos) with unstructured correlation*
- *Interaction terms between visit and all other factors*

Primary Analysis – “Difference in LS means” 4mg

Square Root of GA	4 mg	Sham	Diff
Difference in LS means*	0.321	0.444	0.124
Overall Relative Difference	27.81% ($P = 0.0051$)		

* *Model estimated growth rate*

Primary Analysis – “Difference in LS means” 2mg

Square Root of GA	2 mg	Sham	Diff
Part 1 Difference in LS means*	0.329	0.422	0.093
Part 2 Difference in LS means*	0.308	0.422	0.114
Overall Difference in LS means*	0.292	0.402	0.110
Overall Relative Difference	27.38% (<i>P</i> = 0.0072)		

* *Model estimated growth rate*

Primary Endpoint Achieved: Zimura 4 mg vs Sham

Based on LSMEANS from MRM Model; ITT Population Hochberg procedure used for significance testing

Primary Endpoint Achieved: Zimura 2 mg vs Sham

Based on LSMEANS from MRM Model: ITT Population Hochberg procedure used for significance testing

These least square means are estimates of the MRM model, drawing on all available data, including data from groups with different randomization ratios in Part 1 and Part 2, and should not be interpreted as directly observed data.

Primary Analysis

Statistical interpretation:

- Treatment effects are estimated from model that adjusts for baseline covariates, study part, and missing data
- Benefits of similar magnitude and equally robust for the two doses of Zimura (~27% reduction in GA growth)
- Benefits comfortably significant
- Proportional benefits from baseline to 6 months, and from 6 to 12 months

Missingness of Geographic Atrophy Data

	N (%) ¹
Missing at baseline ²	1 (<1%)
Missing at 6 months and at 12 months ²	36 (14%)
Missing at 6 months only	11 (4%)
Missing at 12 months only	30 (12%)
No missing	182 (70%)
	260 (100%)

¹Sham, 2mg and 4mg groups

²Excluded from model for 2mg and 4mg

Sensitivity to Missing GA Data

Several pre-specified analyses conducted per FDA conventions:

1. Replaced missing data by
 - mean value of same treatment arm
 - mean value of opposite treatment arm
 - mean value of both treatment arms
 - mean value of sham arm
2. Replaced missing data using multiple imputation, with an added “shift” (shift increased until significance was lost)
3. Replaced missing data using “pattern mixture model”
(useful to investigate “missing not at random” assumptions)

Sensitivity to Missing GA Data (4 mg)

Data imputation method	Difference**	P
No imputation (primary analysis)	0.124	0.0051*
Impute mean value of same arm	0.152	<0.0001*
Impute mean value of opposite arm	0.107	0.0033*
Impute mean value of both arms	0.129	0.0003*
Impute mean value of sham arm	0.120	0.0008*

* Statistically significant (without adjustment for multiplicity)

** Difference in means of GA area (square root transformation)

Sensitivity to Missing GA Data (2 mg)

Data imputation method	Difference**	<i>P</i>
No imputation (primary analysis)	0.110	0.0072*
Impute mean value of same arm	0.119	0.0005*
Impute mean value of opposite arm	0.075	0.031*
Impute mean value of both arms	0.097	0.0047*
Impute mean value of sham arm	0.093	0.0056*

* Statistically significant (without adjustment for multiplicity)

** Difference in means of GA area (square root transformation)

Sensitivity to Missing GA Data

Statistical interpretation:

- Missing data were as expected in this indication
- All analyses showed small impact of missing data
- The shift imputation analyses showed that statistical significance would only be lost for large shifts
- **Analysis results were robust to missing data**

Statistical Take Home Messages

- Statistically significant reductions in GA growth for both 2 mg and 4 mg doses, using mixed effects model
- Little difference in efficacy between 2 mg and 4 mg doses
- Analysis results robust to missing data
- Magnitude of effect may justify independent confirmation in a single additional pivotal trial

Thank You

Regulatory Endpoint for Geographic Atrophy

Karl G. Csaky, M.D., Ph.D.
T. Boone Pickens Senior Scientist
Director of the Molecular Ophthalmology Laboratory
Clinical Center of Innovation for Age-Related Macular Degeneration
Retina Foundation of the Southwest

Take Home Message

- Geographic atrophy expansion – loss of retinal tissue
- Loss of retinal tissue – profound effects on patient's "total" vision and quality of life
- Drugs that can reduce geographic atrophy expansion:
Large impact on patient's activity of daily living
- **FDA considers a reduction in geographic atrophy expansion – approval endpoint – with a strong consideration of the safety of the drug**

Geographic Atrophy (GA)

- GA is characterized by atrophic patches and focal hypopigmentation^{1,2}
 - » Atrophic patches are focal areas that lack RPE, photoreceptors, and choriocapillaris¹
 - » Large choroidal vessels may be visible through the atrophic patches¹
 - » Focal hypopigmentation involves thinning of the RPE and reduced melanin density²

Atrophic Area of RPE; Choroidal Vessels Are Visible

Close Correlation of Size of the Atrophy in FAF Images With Photoreceptor Loss on SD-OCT

There Are No FDA-Approved Treatment Options for GA

FDA Review:

- The United States Federal Food, Drug, and Cosmetic Act is a set of laws passed by Congress in 1938 - oversee the safety of food, drugs, medical devices, and cosmetics
- 1962 Kefauver-Harris Amendment - requirement that all new drug applications demonstrate "substantial evidence" of the drug's efficacy for a marketed indication

Take Home Message

- Geographic atrophy expansion – loss of retinal tissue
- Loss of retinal tissue – profound effects on patient's "total" vision and quality of life
- Drugs that can reduce geographic atrophy expansion:
Large impact on patient's activity of daily living
- **FDA considers a reduction in geographic atrophy expansion – approval endpoint – with a strong consideration of the safety of the drug**

Zimura Pivotal Trial: Imaging Analysis

Glenn Jaffe, MD

Director, Duke Reading Center

Robert Machemer Professor of Ophthalmology

Chief, Retina Division

Duke Eye Center

Take-home Message

Robust, rigorous grading methodology gives
confidence in study endpoint data

Duke Reading Center : Overview

- Established 2001
- Experienced staff consisting of physicians and other experts in imaging/functional testing
- Multiple Publications
- Image research/development
- Varied clinical trials
- Over 17,000 US and ROW OCT Technicians and Photographers certified
- Phase I-IV studies
- Single site-multicenter global
- 10-2400 subjects

Our Experience-Diseases

- Retinal vascular (DME/RVO/DR)
- NVAMD
- Intermediate AMD
- GA
- Hereditary retinal degeneration
- RD
- Vitreous pharmacolysis
- Uveitis
- Glaucoma
- Optic neuritis/MS
- Non-ophthalmic safety studies

Our Experience-Diseases

- Retinal vascular (DME/RVO/DR)

- NVAMD

- Intermediate AMD

- GA

- Hereditary retinal degeneration

- RD

- Vitreous pharmacolysis

- Uveitis

- Glaucoma

- Optic neuritis/MS

- Non-ophthalmic safety studies

Our Imaging Experience Relevant to Zimura GA Trial

- Extensive AMD study experience (Dry and Wet)
- **35 treatment trials for AMD (10 GA trials)**
- **Largest AMD trials to-date (CATT, VIEW 1, HAWK etc)**
- Have led to drug registration (US, Ex-US)
- Provide consultation to sponsors
- Develop appropriate grading variables
- Safety reporting system

Our Imaging Experience Relevant to Zimura GA Trial

- Image based eligibility
 - Optical Coherence Tomography (OCT)
 - Infrared imaging (IR)
 - Fluorescein angiography (FA)
 - Fundus autofluorescence (FAF)
 - Color fundus photography
- Image-based endpoints FAF/OCT/IR
- Image-based safety OCT/IR

Reader Experience

- 3 primary Readers during study
- All three Senior Readers
- Each more than 10 years experience
- Excellent Reader Agreement

Director of Grading Experience

- Founder and Director of DRC
- 30 years clinical trial experience (site PI, Individual IND)
- Basic science program-complement role in AMD
- Director of Grading for DRC AMD trials
- Member of CAM
- Director of Duke Dry AMD meeting

Many Relevant DRC Publications

- CAM
- AMD reader reproducibility
- Novel AMD image interpretation methods
- AMD/complement basic science

Zimura Pivotal Trial: Robust Grading Methodology

Rigorous Review Process

- Completely masked assessment
- Each visit evaluated independently
- 2 experienced 1⁰ Readers measure GA lesion size on FAF with RegionFinder
- Discrepancies >10% arbitrated
- Arbitrator is Glenn Jaffe, MD, Director of Grading
- lesions measured on FAF with OCT and NIR used as supportive modalities

GA Defined on OCT by cRORA

Complement C5 Inhibition: Scientific Rationale in Geographic Atrophy Secondary to Dry AMD

Marco A. Zarbin, M.D., Ph.D., FACS
Professor and Chair
Institute of Ophthalmology and Visual Science
Rutgers-New Jersey Medical School
Newark, New Jersey

Geographic Atrophy:

Degeneration & death of retinal cells over time leading to loss of functional vision

Zimura for Geographic Atrophy: Scientific Rationale

- Complement abnormalities strongly associated with developing AMD:
 - Genetic link
 - In vitro studies
 - Post-mortem ocular histology
- Complement activation → C5 cleavage → C5a & C5b formation
 - C5a → inflammasome activation → Retinal cell degeneration & cell death
 - C5b → membrane attack complex (MAC) formation → Retinal cell death

C5 Inhibition: Potential Target for GA and AMD

Genetic Link: Complement & AMD

“In individuals homozygous for the risk allele, the likelihood of AMD is increased by a factor of 7.4”

A common haplotype in the complement regulatory gene factor H (*HF1/CFH*) predisposes individuals to age-related macular degeneration

C5a enhances cytokine release

Physiological Antagonism

→ Anti-inflammatory

→ Pro-inflammatory

C3aR and neutrophils

Neutrophil

- C3aR abundantly expressed by neutrophils
- C3a not chemotactic for neutrophils!
- C3a doesn't induce 'activation' of neutrophils
- *Question: What is C3aR doing on neutrophils?*
- *Answer: C3aR activation inhibits neutrophil mobilization from the bone marrow*

C3aR is protective on neutrophils

Neutrophils

o **C3aR** – prevents neutrophil mobilization and subsequent infiltration into tissues

C5a in ALS: C5aR1^{-/-} SOD1^{G93A} mice

Genetic absence of C5aR increases survival and slows motor neuron death in SOD1^{G93A} mice

C3a in ALS: A similar or opposing role in ALS?

C3aR are upregulated in diseased SOD1^{G93A} mice

C3a in ALS: C3aR^{-/-} SOD1^{G93A} mice

Genetic absence of C3aR reduces survival in SOD1^{G93A} mice

Protective roles for C3 in the eye: iC3b-CR3

- Absence of C3 accelerated photoreceptor degeneration in the rd10 mouse model of *retinitis pigmentosa*
- Absence of microglial CR3 also recapitulated the phenotype
- Implicates iC3b opsonization of apoptotic photoreceptors and phagocytic clearance by microglia through CR3
- Early clearance of apoptotic photoreceptors, reduces inflammation and non-cell autonomous degeneration

Protective roles for C3 in infection control

- All complement components contribute to immune defense
- C3 plays roles through both C3a and iC3b
- Several examples where C3 (but not C5) are important for immune protection

Complement Component C3 Is Required for Protective Innate and Adaptive Immunity to Larval *Strongyloides stercoralis* in Mice

Laura A. Kerepesi, Jessica A. Hess, Thomas J. Nolan,
Gerhard A. Schad and David Abraham

J Immunol 2006; 176:4315-4322; ;

- Selective targeting of pathogenic complement components may avoid opportunistic infection risk

Summary

- Complement C3a receptors play roles in endotoxemia, ischemia-reperfusion, neurotrauma, and ALS models
- *C3aR is protective* in these models (knockout worsens disease)
- *C3-CR3 is also protective* in the eye in retinitis pigmentosa model
- Global blockade of C3 (as opposed to C5) may prevent the beneficial activities of C3a, whilst also increasing infection risk
- Complement drugs should therefore be targeted towards disease indication to provide appropriate therapeutic response

AGE-RELATED MACULAR DEGENERATION (AMD)

Late Dry AMD “Geographic Atrophy”

Normal

Early Dry AMD Deposits

“Neovascular” AMD

Vision Loss with End-Stage Age-Related Macular Degeneration

Pathway of AMD Disease Progression

Patients in ANCHOR, MARINA, and HORIZON

A Multicenter Cohort Study (SEVEN-UP)

Soraya Rofagha, MD, MPH,¹ Robert B. Bhisitkul, MD, PhD,¹ David S. Boyer, MD,² Srinivas R. Sadda, MD,³ Kang Zhang, MD, PhD,⁴ for the SEVEN-UP Study Group*

Purpose: To assess long-term outcomes 7 to 8 years after initiation of intensive ranibizumab therapy in exudative age-related macular degeneration (AMD) patients.

Design: Multicenter, noninterventional cohort study.

Participants: Sixty-five AMD patients originally treated with ranibizumab in the phase 3 Anti-VEGF Antibody for the Treatment of Predominantly Classic Choroidal Neovascularization in AMD (ANCHOR) trial, Minimally Classic/Occult Trial of the Anti-VEGF Antibody Ranibizumab in the Treatment of Neovascular AMD (MARINA) trial, and Open-Label Extension Trial of Ranibizumab for Choroidal Neovascularization Secondary to Age-Related Macular Degeneration (HORIZON).

Methods: Fourteen clinical trial sites recruited their original subjects for a return evaluation. Individual subject comparisons were obtained from the ANCHOR, MARINA, and HORIZON databases.

Main Outcome Measures: The primary end point was percentage with best-corrected visual acuity (BCVA) of 20/70 or better; secondary outcomes included mean change in letter score compared with previous time points and anatomic results on fluorescein angiography, spectral-domain ocular coherence tomography (OCT), and fundus autofluorescence (FAF).

Results: At a mean of 7.3 years (range, 6.3–8.5 years) after entry into ANCHOR or MARINA, 37% of study eyes met the primary end point of 20/70 or better BCVA, with 23% achieving a BCVA of 20/40 or better. Thirty-seven percent of study eyes had BCVA of 20/200 or worse. Forty-three percent of study eyes had a stable or improved letter score (≥ 0 -letter gain) compared with ANCHOR or MARINA baseline measurements, whereas 34% declined by 15 letters or more, with overall a mean decline of 8.6 letters ($P < 0.005$). Since exit from the HORIZON study, study eyes had received a mean of 6.8 anti-vascular endothelial growth factor (VEGF) injections during the mean 3.4-year interval; a subgroup of patients who received 11 or more anti-VEGF injections had significantly better mean gain in letter score since HORIZON exit ($P < 0.05$). Active exudative disease was detected by FAF in 68% of study eyes, and 46% were receiving ongoing ocular anti-VEGF therapy for visual outcome ($P < 0.0001$).

After ranibizumab therapy in the ANCHOR or MARINA trials, one third of study eyes had good outcomes, whereas another third had poor outcomes. Compared with baseline, one third of study eyes had improved letter scores, whereas one third declined by 15 letters or more. Even at this late stage in the therapeutic course, patients remain at risk for substantial visual decline.

*Group members listed online in Appendix 1, available at <http://aaojournal.org>.

Exudative age-related macular degeneration (AMD) is a chronic, progressive disease.^{1–4} Ocular anti-vascular endothelial growth factor (VEGF) therapy, the current standard for exudative AMD, inhibits the end results of the disease—choroidal neovascularization (CNV) and vascular leakage—but does not seem to act on the causative mechanisms underlying VEGF overexpression and the onset and

perpetuation of active disease. It is unclear whether ocular anti-VEGF therapy leads to a cure and how many patients require long-term treatment for recurrent exudation.

Ocular anti-VEGF therapy has been in wide clinical use for many years. Ranibizumab (Lucentis; Genentech, Inc., South San Francisco, CA) was approved in the United States in June 2006. Even earlier than that, bevacizumab

VEGF Protects through Modulation of Complement Proteins

Outer retinal and renal glomerular functions rely on specialized vasculature maintained by VEGF that is produced by neighboring epithelial cells, the retinal pigment epithelium (RPE) and podocytes, respectively. Dysregulation of RPE- and podocyte-derived VEGF is associated with neovascularization in wet age-related macular degeneration (ARMD), choroidal neovascularization, and glomerular thrombotic microangiopathy (TMA). Since complement activation and genetic variants in inhibitory complement factor H (CFH) are also features of both ARMD and TMA, we hypothesized that VEGF and CFH interact. Here, we demonstrated that VEGF inhibition decreases local CFH and other complement regulators in the eye and kidney through reduced VEGFR2/PKC- α /CREB signaling. Patient podocytes and RPE cells carrying disease-associated CFH genetic variants had more submembrane complement pathway deposits than controls. These deposits were increased by VEGF antagonism, a common wet ARMD treatment, suggesting that VEGF inhibition could reduce cellular complement regulatory capacity. VEGF antagonism also increased markers of endothelial cell activation, which was partially reduced by genetic complement inhibition. Together, these results suggest that VEGF protects the retinal and glomerular microvasculature, not only through VEGFR2-mediated vasculotrophism, but also through modulation of local complement proteins that could protect against complement-mediated damage. Though further study is warranted, these findings could be relevant for patients receiving VEGF antagonists.

“Together, these results suggest that **VEGF protects the retinal and glomerular microvasculature**, not only through VEGFR2-mediated vasculotrophism, **but also through modulation of local complement proteins that could protect against complement-mediated damage**. Though further study is warranted, these findings could be relevant for patients receiving VEGF antagonists.”

Intravitreal Anti-VEGF Results in Complement Activation

Aqueous humor from 10 ARMD patient eyes was sampled before and 48 hours after a single intravitreal bevacizumab

Complement Inhibition May Protect the Endothelium

ARMD pathogenesis. The most widely studied is the CFH 402H polymorphism, and we demonstrated that RPE cells with this polymorphism showed more cell-surface complement deposition. This supports previous studies that showed CFH 402H does not protect from binding to the cell surface glycoprotein, very low-density lipoprotein, and this can affect cell-surface complement regulation (24, 41, 42). In the kidney, these CFH mutations also affect the protein's ability to bind to the cell surface and regulate complement (43). Therefore, we compared an aHUS podocyte cell line with a known CFH mutation (40) to the ARMD RPE cells with the CFH polymorphism in our complement activation assay and obtained similar results, suggesting that the effect observed in RPE cells could be due to impaired cell-surface binding of CFH 402H. Formal binding studies would be needed to confirm these results.

Complement activation is a known feature of ARMD (21, 23, 24, 44), and our experiments suggest VEGF antagonism could exacerbate this by reducing synthesis of CFH and other inhibitory complement proteins. Since both C3 and C4 deposits were increased by VEGF antagonism, these effects likely represent changes in multiple complement inhibitors simultaneously. These effects were more pronounced in cells expressing CFH 402H, possibly because they already have reduced complement regulatory capacity and anti-VEGF treatment could decrease this further. This could explain why the CFH 402H polymorphism has been reported to correlate with a reduced response to anti-VEGF therapy (19, 45, 46), although in this complex disease, it is likely that several other factors also contribute to the variable response to anti-VEGF therapy (47). Furthermore, while controversial, there are patient studies suggesting that VEGF antagonists may enhance progression of GA (8, 9, 48, 49), which could be related to direct complement-mediated damage of the RPE cells. Importantly, this does not affect every patient and more work is needed to identify those at risk, but homozygosity of the CFH 402H polymorphism may be one factor.

Complement activation may also affect the choroidal vasculature (50). Our studies showed that inhibiting complement partially prevented the anti-VEGF-induced increase in endothelial cell activation, suggesting that complement inhibition could protect the endothelium. Previous animal models have shown that alternative pathway activation contributes to the development of CNV (51), and cell-surface studies reveal that sublytic levels of MAC can increase RPE-derived VEGF (44), which could contribute to the development of CNV. Considering these data, early complement inhibition in ARMD may prevent some of these negative effects and could reduce the abnormal increase in secreted RPE-derived VEGF. However, a balance must be struck, since murine studies also suggest that complete, prolonged complement inhibition is detrimental (53). Further work is needed to examine this, particularly in humans, since there are important species differences in the complement cascade. Complement inhibition in ARMD, including GA, is an area of active study, with several agents currently in phase 2/3 trials (54).

Complement protein mutations are also associated with glomerular TMA, as shown by studies of familial aHUS (55). The same glomerular pathology was later identified in patients receiving systemic bevacizumab to treat tumor angiogenesis (56, 57). Eremina et al. showed that these effects were replicated in mice with a glomerular-specific VEGF knockout (29), highlighting the importance of local podocyte-derived VEGF in the maintenance of the glomerular endothelium. Using the same model and human cells in vitro, we show that reduced glomerular VEGF decreased expression of local CFH and other complement regulators in both podocytes and glomerular endothelial cells, predisposing them to complement deposition. These findings link the pathogenesis of glomerular TMA associated with anti-VEGF therapy to that of complement-mediated aHUS and may explain why the renal glomerulus is susceptible to complement-mediated disease. Interestingly, preeclampsia, another glomerular disease associated

“Our studies showed that inhibiting complement partially prevented the anti-VEGF–induced increase in endothelial cell activation, suggesting that complement inhibition could protect the endothelium.”

“there are patient studies suggesting that VEGF antagonists may enhance progression of GA (8, 9, 48, 49), which could be related to direct complement-mediated damage of the RPE cells.”

Pseudo-drusen associated atrophy

Reticular Pseudodrusen Associated Atrophy

OUTER RETINAL ATROPHY AFTER REGRESSION OF SUBRETINAL DRUSENOID DEPOSITS AS A NEWLY RECOGNIZED FORM OF LATE AGE-RELATED MACULAR DEGENERATION

RICHARD F. SPAIDE, MD

Purpose: To investigate the long-term clinical course of eyes with pseudodrusen appearance caused by subretinal drusenoid deposits.

Methods: Eyes from the original study identifying subretinal deposits of material as the cause of pseudodrusen appearance were evaluated in a retrospective study of outer retinal morphology. The distance between the inner plexiform layer and the retinal pigment epithelium, termed the photoreceptor length, was measured from optical coherence tomography approximately 2 mm superior to the fovea at baseline and at follow-up visits. The choroidal thickness was measured directly under this retinal area.

Results: Of the 21 eyes available for follow-up, 9 (42.9%) eventually developed choroidal
